Hello, I hope this information helps you get started in using this application.

1. Enter your database information into the .env file located in the root directory.

- This information feeds into the db.js file in the root directory.
  - For more information on ways to connect to the mssql server please see the information on the npm library used for the connection: https://www.npmjs.com/package/mssql
  - Please look at this library if your server requires more options to connect you will need to edit the db.js file in the root directory.

2. The routes/api/routes.js file contains the routes that communicate between the server and the application. You can edit the SQL queries to change what data you receive for each route here.
